## USTCON

$$P(i, j) := \begin{cases} \frac{1}{d(j)} & \text{if } \{i, j\} \in E, \\ 0 & \text{otherwise.} \end{cases}$$

$$\Rightarrow \mu_t = P^t \mu_0$$

## Facts

$$\textcircled{1} \forall i: |\lambda_i(P)| \leq 1.$$

$$\textcircled{2} G \text{ connected \& non-bip} \Rightarrow \begin{cases} \exists! \text{ stationary } \pi : P\pi = \pi, \\ |\lambda_2| < 1. \end{cases}$$

$$\Rightarrow P^t = 1 \cdot |\pi\rangle \langle \pi| + \underbrace{\sum_{j \geq 2} \lambda_j^t |v_j\rangle \langle v_j|}_{\rightarrow 0}$$

$$\text{In fact } \begin{cases} \pi(i) = \frac{d(i)}{\sum_j d(j)}, \\ \delta := 1 - |\lambda_2| \geq 1/n^3. \end{cases}$$

## USTCON

**BPL-Procedure for USTCON**

- 1 Do many Random Walks

**BQL-Procedure for USTCON**

- 1 Ta-Shma [1]: In **BQL** can do  $\text{QPE}(e^{iP})$  on random  $|v\rangle$ ,  
 $\Rightarrow$  estimate  $\dim(\ker(I - P)) = \#\text{CCs}$
- 2 Does dim change if we add edge  $\{s, t\}$ ?

## STCON

## Problematic example

- In general  $\delta := 1 - s_2$  exp-small  
⇒ Estimating  $\dim(\ker(I - P))$  doesn't work anymore ☹️

## Theorem (Ta-Shma [1])

If  $A$  poly-conditioned, i.e.  $\text{poly}(n) \geq s_1(A) \geq \dots \geq s_n(A) \geq \frac{1}{\text{poly}(n)}$ , then can approximate  $A^{-1}$  up to  $\frac{1}{\text{poly}(n)}$  accuracy in **BQL**.

## Ta-Shma for STCON

## Theorem

If  $\#\text{paths}(i, j) \leq \text{poly}(n) \forall i, j$ , then can decide STCON in **BQL**.

## Proof.

Consider  $\mathcal{L} := I - A$  for adjacency matrix  $A$  of a DAG.

$$\Rightarrow \mathcal{L}^{-1} = I + A + \dots + A^{n-1} \text{ because } A^n = 0,$$

$$\Rightarrow \mathcal{L}^{-1}(i, j) = \#\text{paths}(i, j).$$

Hence,  $\mathcal{L}$  is poly-conditioned iff  $\begin{cases} \|\mathcal{L}\|_\infty \leq \text{poly}(n), \\ \|\mathcal{L}^{-1}\|_\infty \leq \text{poly}(n), \end{cases}$

because  $\begin{cases} s_1(\mathcal{L}) = \|\mathcal{L}\|_2 \leq \sqrt{n}\|\mathcal{L}\|_\infty, \\ s_n(\mathcal{L}) = 1/\|\mathcal{L}^{-1}\|_2 \geq 1/\sqrt{n}\|\mathcal{L}^{-1}\|_\infty. \end{cases}$

## Examples

Example 1: Random Walk fails, #Paths works.

Example 2: Random Walk works, #Paths fails.

# Unambiguity & Fewness

- $N(i, j) := \#$ paths from node  $i$  to  $j$
- Following [2], a graph is called ...

unambiguous  
 $:\Leftrightarrow N(s, t) \leq 1$

reach-unambiguous  
 $:\Leftrightarrow \forall j : N(s, j) \leq 1$

strongly unambiguous  
 $:\Leftrightarrow \forall i, j : N(i, j) \leq 1$

# Unambiguity & Fewness

- $N(i, j) := \# \text{paths from node } i \text{ to } j$
- Following [2], a graph is called ...

unambiguous  
 $:\Leftrightarrow N(s, t) \leq 1$

few unamb.  
 $\dots \leq \text{poly}(n)$

reach-unambiguous  
 $:\Leftrightarrow \forall j : N(s, j) \leq 1$

reach-few  
 $\dots \leq \text{poly}(n)$

strongly unambiguous  
 $:\Leftrightarrow \forall i, j : N(i, j) \leq 1$

strongly-few  
 $\dots \leq \text{poly}(n)$

## Unambiguity &amp; Fewness

- 1998 Allender & Lange [3]:  $\mathbf{ReachUL} \subseteq \text{DSPACE}\left(\frac{\log^2 n}{\log \log n}\right)$
- 2012 Garvin, Stolee, Tewari & Vinodchandran [4]:  
 $\mathbf{ReachUL} = \mathbf{ReachFewL}$
- Previous slide:  $\mathbf{StFewL} \subseteq \mathbf{BQL}$

## Unambiguity &amp; Fewness

- 1998 Allender & Lange [3]:  $\mathbf{ReachUL} \subseteq \mathbf{DSPACE}\left(\frac{\log^2 n}{\log \log n}\right)$
- 2012 Garvin, Stolee, Tewari & Vinodchandran [4]:  
 $\mathbf{ReachUL} = \mathbf{ReachFewL}$
- Previous slide:  $\mathbf{StFewL} \subseteq \mathbf{BQL}$

## Can we go further?

## Theorem

If  $\#\text{paths}(s, i), \#\text{paths}(i, t) \leq \text{poly}(n) \forall i$ , then  $\text{STCON} \in \mathbf{BQL}$ .

## Proof.

Consider again  $\mathcal{L} := I - A = \sum_j s_j |u_j\rangle \langle v_j|$

$$\Rightarrow \mathcal{L}^{-1} = \underbrace{\sum_{s_j < \kappa^{-1}} s_j^{-1} |v_j\rangle \langle u_j|}_{???} + \underbrace{\sum_{s_j \geq \kappa^{-1}} s_j^{-1} |v_j\rangle \langle u_j|}_{\text{easy by Ta-Shma}}$$

Observe  $\|\mathcal{L}^{-1} |t\rangle\|_2^2 = \sum_j s_j^{-2} |\langle u_j | t \rangle|^2 \leq \text{poly}(n)$

$$\Rightarrow \begin{cases} |\langle s | v_j \rangle| \leq s_j \cdot \text{poly}(n), \\ |\langle u_j | t \rangle| \leq s_j \cdot \text{poly}(n) \end{cases} \Rightarrow |s_j^{-1} \langle s | v_j \rangle \langle u_j | t \rangle| \leq s_j \cdot \text{poly}(n)$$

Choose  $\kappa = \text{poly}(n)$  s.t.  $\sum_{s_j < \kappa^{-1}} |s_j^{-1} \langle s | v_j \rangle \langle u_j | t \rangle| \leq 1/3$ . □

## Open Questions

- 1 Can we obtain **ReachFewL**  $\subseteq$  **BQL**?
- 2 What info can we get from ill-conditioned part?

Can we detect if  $\frac{N(s,t)}{\sum_{i,j} N(i,j)} \geq 1/\text{poly}(n)$ ?

- ③ Is there a natural **BQL**-complete graph problem? What's the relationship with **#L**, **GapL**?

$$\begin{cases} \text{pc-MATPOW}_{\mathbb{C}} \text{ is } \mathbf{BQL}\text{-complete,} \\ \text{pc-MATPOW}_{\mathbb{N}} = \text{counting paths in StFew-graphs} \end{cases}$$

Conjecture:  $\text{pc-MATPOW}_{\{\pm\frac{1}{2},0\}}$  is **BQL**-complete.
